Classifier Part 2

Task 1: Object features

Loading the quickbird data of Salzburg in an ecognition project and air quality data set. Layer 1- 4 can be seen in the Screenshot below, that are the 4 image bands (Layer 1 = blue, Layer 2 = green, Layer 3 = red and Layer 4 = nir bands) and Layer 5 is the air quality raster.

Added New process to the "Process Tree" window and selected the "chessboard segmentation" algorithm and executed the segmentation with an "object size" of 10.

Boat and Water are selected for looking at "Object Information"

Question 1: What becomes obvious if you compare the values for the two objects of the chessboard segmentation?

A. The mean values for different classes are different. For example, the mean values for Water and the road are different for each layer.

Question 2: Which features don't make that much sense in this case?

A. Excessive Outlining in Non-Feature Areas e.g somewhere overlay detailed boundaries or small patches doesnot make sense.
Also, the certain outlines near roads or river doesnot make that much sense.
Also, it seems that shape doesnot make sense. Value of number of pixel doesnot make sense because in chessboard segmentation all the segments consist of same same number (100).

Task 2:

Creating a new one, using the multiresolution segmentation algorithm. Two objects were selected as shown in the SS below.

Task 3:

After finding a threshold for the new NDVI feature, to distinguish between vegetation and non-vegetation areas and a threshold to extract water bodies, here are the results.

Task 4:

Two new classes were created that are Vegetation and Water as seen in the SS and a new single process for each class using the "assign class" algorithm in the process tree and classified the objects according to the corresponding NDVI values >= 0.25 for vegetation and <=-0.15 for water.

Now we make use of the class relation feature: For this purpose, we selected the feature "Relative border to" (object features> relations to objects >-Neighbors > Rel. Border to > double clicked and create new rel. border to" and selected the class that defines the objects to which a relation should be calculated. Then class water (relative border to water) was selected, and the feature was created. (see below)

Air quality layer a priori information to refine our classification.

The goal was to create sub-classes of the class vegetation to divide the class into areas with high/low air quality. So, two new classes were created (high_air_quality, low_air_quality). Two additional "assign

class" algorithms were added to split the vegetation classes in different air quality classes (Air quality layer is in our project "layer 5"). (See below SS)

Q 3. How many objects were classified as "water"?

A. Three objects were classified as Water as can be seen in the screenshot under the object section.

Q 4. What is the area of the whole vegetation class (if you select the vegetation class to generate the feature, it will summarize the values from the grouped sub-classes)?

A. The area of the whole vegetation class is 0.05711760 square km.

Task 5: Creating a new level

Scale Parameter 50

Output:

Resulted in smaller segments with more details but in this case it's also segmenting one water body in to smaller segments and leading to over-segmentation. That may not make a sense. It seems it is suitable for detailed features such as building, roads and small vegetation patches.

Scale Parameter 200

Output:

It produced larger segments, it seems that it is better suitable for larger homogenous features such as forest, water bodies as seen in the screenshot. It reduced noise by merging small objects.

Question 5: What is the meaning of the distance value when you create the feature?

When constructing relationships between objects, the distance value is utilized as a parameter, particularly for the feature "Existence of super-objects."

To determine if a "super-object" such as vegetation or another higher-level object in the hierarchy is seen as being related to the object in question, the distance value establishes a threshold or spatial closeness. In this instance, a distance value of 1 means that the relationship is assessed within a unit's distance from the object.
