

# PS Methods in Spatial Analysis Assignment #2 | Spatial Analysis

#### Paris-Lodron-Universität Salzburg

#### **Department of Geoinformatics**

### Objective

The objective is to use spatial analysis techniques to analyze Salzburg and its terrain using ArcGIS Online and ArcGIS Pro methods.

Data:

- 1. DEM of Salzburg: dgm5m.asc
- 2. Catchments\_Salzburg
  Source

(https://zgis.maps.arcgis.com/home/item.html?id=3dfdaf154803453795c632a98c26da3e)

### Study Area:

A river's Catchment area is identified using the attribute code HZB\_CODE that is 82721 46 as shown in the screenshot below.

### Task 1 > grade 4:

The selected catchment area is the area of interest for the following tasks:

- 1. Create a hill shade for the selected area
- 2. Create a map showing the color-coded elevation of the area

### Create a hill shade for the selected area

Hill shade, Slope, Aspect for the area of interest is processed by using Geo-processing tool>Hillshade, Slope, Aspect.

Figure 1. Hillshade

Figure 2. Attributes of the Area

### Task 2 > grade 3:

Calculate a map showing slope and aspect. Calculate average slope and provide a slope histogram. Please explain the histogram accordingly.

Figure 5. Slope Histogram

The histogram showing the distribution of slope values (in degrees) for a study area, with the slope values represented in the raster dataset. X-Axis Represents the slope values, measured in degrees. The range of values spans approximately from **1.6 to 20.5 degrees**, divided into intervals. Each interval aggregates a subset of the slope values within the defined range whereas Y-Axis represents the frequency (or count) of pixels in the raster that fall within each slope value range.

The distribution shows a slightly right-skewed pattern, with most slope values concentrated around the central range of approximately 6 to 10 degrees, as seen from the higher bars in the middle. Fewer pixels have very low (<5) or very high (>15) slope values.

Mean slope value: Approximately 7.59 degrees. The histogram reflects the natural variation in slope across the terrain, likely highlighting areas with moderate slopes as the most common.

### Task 3 > grade 2:

Calculate the average slope for each elevation zone (you can choose between 200m/500m elevation intervals) and provide a slope histogram for each elevation zone. (Hint: use the tool "contour" to generate the elevation interval polygons – use contour type "contour polygon").

### Task 3 > grade 2:

Calculate the average slope for each elevation zone (you can choose between 200m/500m elevation intervals), and provide a slope histogram for each elevation zone. (Hint: use the tool "contour" to generate the elevation interval polygons – use contour type "contour polygon").

### Task 4 > grade 1:

Evaluate the average slope per elevation zone for different elevation raster resolution (5m - 10m - 100m). Please provide the average slope for each elevation zone and a histogram. Please explain your results accordingly!

# **Discussion:**

# **Raster Resolution**

- During the evalution of Average Slope per elevation across different Raster Resolution such as 5,10 and 100m, it has been noticed that resolution significantly impact terrain representation.
- 5m resolution showed highly detailed representation of terrain and captured variations in elevation and slope etc clearly.
- In 10m resolution, it defined moderate detailed representation of the features.
- In 100m resolution, it has been observed that representation of train is very coarse, shows only broad elevation trends.

# **Average Slope Calculation**

The average is calculated using the formula:

12

# Avg = (!Contour Maximum!+!Contour Minimum!)

# **Results:**

# 5m Resolution/Histogram

In the attribute table of 5m slope, precise contour ranges can be seen, and slope averages are quite visible due to detailed terrain representation.

In the Histogram of 5m slightly wider value ranges can be seen that reflects variabilities in the terrain. And the mean and median values are close enough (1393 and 1400) that indicated symmetrical distribution.

# 10m Resolution/Histogram

The average slope that is calculated per zone is smoothing out slightly that indicates reduction of visibility.

The histogram indicated the narrower distribution as compared to 5m resolution. The mean and median are observed to be the same but changes in variability of slope can be observed that is decreasing slightly.

# 100m Resolution/Histogram

In 100m resolution, a noticeable roughness can be seen, and average slopes are largely smoothing out that is reducing visibility and undermining steep slopes, but it is noticed that mean and median is not changing significantly.

It is also noticed that all slope averages are approximately remained same.
